CW1 — Individual Contribution Report

Antonio Jovan Fernando | Lego Zoo Project | Group – 04
IIT No – 20241687 | UOW No - w2182071

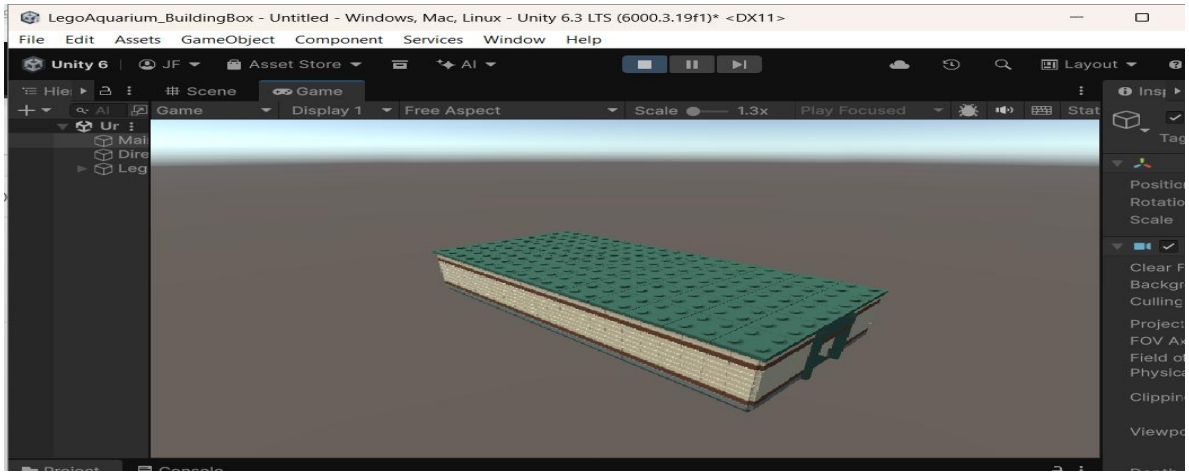

1. My role and contribution

My main task in the LEGO Zoo project was to design the aquarium. I planned a 3D building with brick walls and a studded roof so it would look like part of the same zoo as the other buildings. Inside, I planned a central walkway with display tanks on both sides. This layout gives visitors a clear route from the entrance and lets them stop to look at the tanks as they move through the building.The aquarium also needed to fit into the group's Unity project. I requested a version with empty tanks so I could add the fish and interactive features later. I imported the aquarium model into my own Unity scene and checked the exterior in Game view. For CW2, my next step is to test the aquarium in the combined zoo scene and check how visitors move through the exhibit using the group's shared player controls.

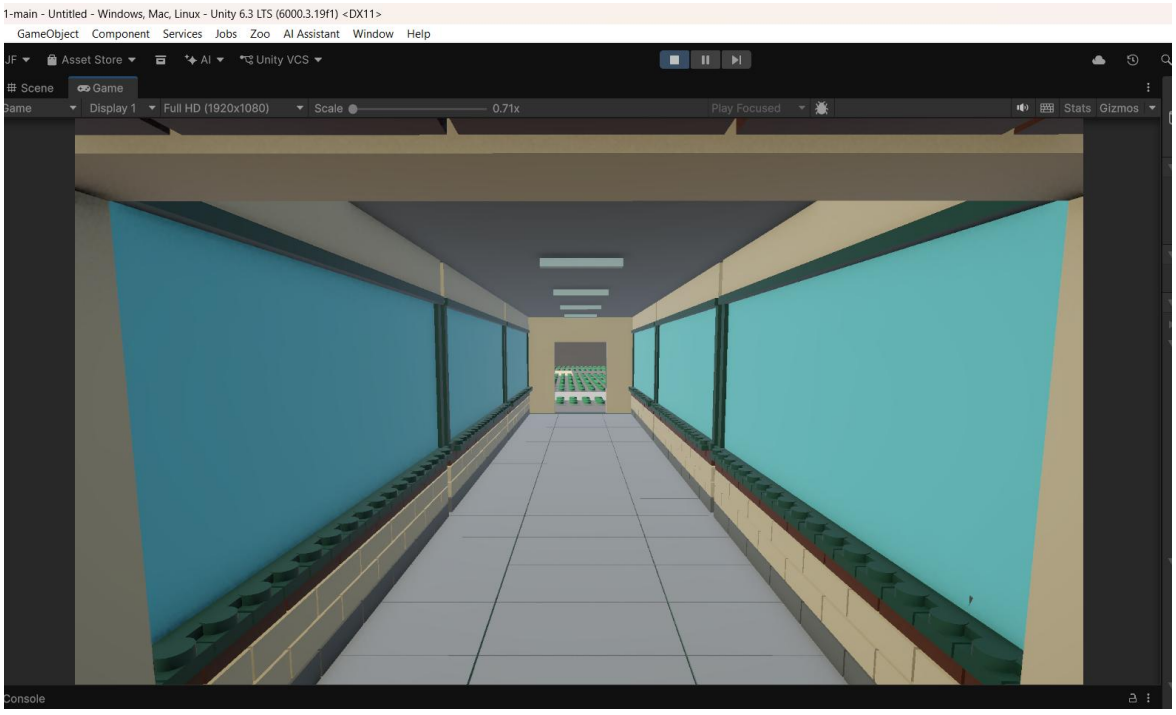

2. Development process and technical work

- **Research and planning** — I used the group's LEGO zoo entrance as a reference and explored how to import a 3D aquarium model into Unity.
- **AI assistance** — I chose the aquarium layout and reviewed each version in Unity. ChatGPT supported specific tasks, including model revisions, the .dae export, and troubleshooting a Unity import error.
- **My own contribution** — I planned a central walkway with tanks on both sides. After reviewing the first version, I asked for lower brightness and requested a version with empty tanks for the group.
- **Testing and improvements** — I imported the .dae model into Unity, positioned the camera, and checked the aquarium exterior in Game view. The animation and interactions still needed to be tested in the group's combined project.

3. Visual evidence

The first screenshot shows my LEGO aquarium from an elevated angle in Unity's Game view. The dark green roof is covered with rows of LEGO-style studs. The light brick walls and thin brown trim are visible along the side, and a dark green frame marks the entrance at the right end. This camera angle shows the roof, side wall, and entrance in one shot, which helped me check how the exterior looked after importing the model into Unity.

The second screenshot shows the inside of my LEGO aquarium in Unity's Game view. The camera faces straight down the central walkway, with large blue display windows on both sides. The grey floor tiles and the row of ceiling lights lead towards the doorway at the far end. From this angle, visitors can see the route ahead and choose which tanks to stop at along the way.

Below the display windows, the light brick bases and dark green studs carry the LEGO style from the outside of the building into the exhibit. The low bases raise the displays above the floor, while the windows stretch along the walkway so visitors can view the tanks as they move through the aquarium. I used this view to show how the layout looks from a visitor's perspective. The screenshot captures the aquarium before the planned fish animations and interactive information panels are added.

4. Collaboration and reflection

In CW2, I plan to add animated fish and interactive information panels to my LEGO aquarium. I want the fish to move around each tank so visitors can watch them from the central walkway. Each information panel will display the name of the species in the tank and a few simple facts, such as where it lives and what it eats. Visitors will be able to open a panel using the group's shared interaction controls, then close it and continue through the exhibit.I will test these features in the group's combined Unity project. I will walk through the aquarium using the shared player controls and check whether I can approach the tanks and use the panels easily. I will also check that the fish stay inside their tanks, that the text is easy to read, and that players can move normally after closing a panel. If a test reveals a problem, I will adjust the feature and test it again in the shared scene.

5. AI assistance: disclosure and critical reflection

I decided to arrange the aquarium around a central walkway with display tanks on both sides. This layout gives visitors a clear route through the building and lets them stop at each display. I used the group's zoo entrance as a visual reference so the aquarium would fit the same LEGO style. After reviewing an earlier version, I asked for the brightness to be reduced so the colours would better match the rest of the zoo. I also requested a version with empty tanks so I could share the building with the group before adding fish and interactive features. I imported the .dae model into Unity and checked it from two viewpoints. In Game view, I positioned the camera above one corner so I could see the roof, side wall, and entrance together. I also checked the interior from a visitor's perspective to see how the display windows, floor tiles, and ceiling lights framed the walkway. These views helped me confirm that the main features were visible after importing the model. For CW2, I will add the fish to the tanks, create their swimming animations, and set up interactive information panels. Visitors will be able to open a panel to learn about the fish in each tank, then close it and continue through the exhibit. I will test these features in the group's combined Unity scene to check that the fish stay inside their tanks and that visitors can open and close the panels using the shared player controls.
